1 <u>GENERAL INFORMATION</u>

1.1 <u>Scope</u>

This document gives the results of Single Event Latch-up (SEL) testing performed on selected EEE components using the ESA Heavy Ion Test Facility (HIF) at Université catholique de Louvain (UCL) in Louvain-la-Neuve, Belgium. The results include the effective LET levels used for testing each component and the LET levels at which any latch-up occurred up to a level twice that required by the project.

The main purpose of the testing was to give confidence that the SEL Linear Energy Transfer (LET) threshold level of each tested component type was above the minimum of 36 MeV cm²/mg required by the PCDF project Product Assurance Plan. The detection of Single Event Upsets was not a purpose of the testing, even though some of the tested components were potentially sensitive to SEU. Although not a specific purpose of the testing the test configuration allowed for the detection of some other Single Event Effects, such as Single Event Burn-out or Single Event Gate Rupture.

The selection of components to be tested and details of the test plan and procedure are described fully in Astrium GmbH Document "Irradiation Test Plan for Selected Electronic Components used in Equipment for ISS/COF designed by Chevalier Photonics", ITP/01-01, Issue 1A of 03.05.2001 (Project Document No. PCDF-TP-DO-71). Where it is considered relevant to the understanding and interpretation of the test results this document repeats information already given in the Irradiation Test Plan, e.g. the electrical bias applied during irradiation and the monitoring conditions used to detect any latch-up during irradiation.

1.2 <u>Applicable Documents</u>

ESA/SCC Basic Specification No. 25100, "Single Event Effects Test Method and Guidelines".

Astrium Document ITP/01-01 Issue 1A dated 03.05.2001 (PCDF Project Document No. PCDF-TP-DO-71). "Irradiation Test Plan for Selected Electronic Components used in Equipment for ISS/COF designed by Chevalier Photonics"

PCDF Project Document No. PCDF-PL-DO-02. "Product Assurance Plan"

1.3 <u>Definition of Terms</u>

Single Event Latch-Up (SEL):

SEL is defined as the heavy ion induced firing of a parasitic structure inherent in some monolithic integrated circuit technologies which exhibits negative differential resistance. Firing of the structure results in an uncontrolled increase of component supply current which might subsequently lead to component destruction (burnout).

Single Event Burnout (SEB):

SEB occurs if an SEL in a component allows sufficient current to pass to cause irreversible catastrophic damage to the component.

SEB can also be the breakdown and subsequent burnout of the parasitic bipolar transistor inherent in a power MOSFET structure (resulting from a heavy ion hit on the parasitic transistor).

Single Event Gate Rupture (SEGR):

SEGR is defined as direct breakdown and subsequent destructive rupture of the gate dielectric layer of a power MOSFET along the track of a heavy ion hit.

Single Event Upset (SEU):

SEU is a form of soft error. It is expressed by the changed state of a bit due to the impact of a heavy ion or proton. The transition of the charged particle causes ionisation, which in turn leads to the flipping of bits. The effect can be corrected after the transition of the ion or proton.

Single Event Effect (SEE):

SEE is a generic term covering all single event occurrences such as latch-up, burnout, gate rupture, upset, etc.

Linear Energy Transfer (LET):

LET is the energy loss of a particle passing through the material of an absorber with a thickness such that a portion of it with a 1 cm² surface area normal to the particle direction has a mass of 1 mg. It is expressed in units of MeV/(mg/cm²) or MeV cm²/mg.

Page: 6 of 70

Effective LET:

This is the equivalent LET obtained by tilting the device under test so that the beam axis is no longer normal to it, hence increasing the path length of the ion and the total energy deposited. It is calculated by:

 $LET_{eff} = LET / \cos\Theta$

where Θ is the tilt angle of the device, i.e. the angle between the beam axis and the normal to the die surface

Threshold LET:

The threshold LET is the LET at which the cross-section has a value of 1% of the saturated crosssection.

Flux:

The rate of incidence of particles on a material is given in terms of the particle flux, expressed in particles/(cm²/s).

Fluence:

The time integral of the flux is referred to as the particle fluency, expressed in particles/cm².

Total dose:

Total dose is defined as the energy deposited in materials by ionising radiation, expressed in terms of rad (<u>r</u>adiation <u>a</u>bsorbed <u>d</u>ose). One rad is equal to an absorbed energy of 100 ergs per gram of the material. Using this unit the material in which the energy is deposited must be specified, e.g. rad(Si) for silicon. The Si unit of absorbed dose is the gray (Gy), which is equal to an absorbed energy of 1 Joule per Kg, or 100 rads.

2 TEST COMPONENT DETAILS

The total number of different component types tested was eighteen. These types were selected as being potentially the most SEL sensitive in the equipment designed for ISS/COF by Chevalier Photonics. All the test samples were supplied by Chevalier Photonics and are from the same component lots as used in the actual flight equipment.

The following list show the types selected and tested, together with the type of package in which they were housed and the number of available samples. In order to retain consistent numbering of component types throughout the various documents produced during the selection and test activities, the eighteen sample types are actually numbered from 1 to 24. This is because six component types included in an earlier list were deleted when further information on existing test results became available. The Part Type numbers given in this list are those used in the original Users' Parts Lists supplied by Chevalier Photonics. Photographs of all these types are included in Appendix A to this document, and details of the complete marking on each supplied component are given in Appendix B.

3 TEST SET UP

3.1 Irradiation Facility

The test facility used for this testing was the ESA Heavy Ion Test Facility at UCL in Belgium. This uses the CYCLONE accelerator which is a multiparticle, variable energy, cyclotron capable of accelerating protons (up to 85 MeV), alpha particles and heavy ions. For the heavy ions the energy range covered is between 0.6 MeV/AMU and 27.5 MeV/AMU with a maximum energy of 110 Q²/M, where Q is the ion charge state and M is the mass in Atomic Mass Units. The heavy ions are produced in a single stage (6.4 GHz) Electron Cyclotron Resonance (ECR) source and an analysing magnet is then used to select the desired M/Q ratio before the ions are injected axially for subsequent acceleration. The use of an ECR source allows the production of highly charged ions and of ion "cocktails", composed of ions with the same or similar M/Q ratios, which are accelerated together but extracted separately by fine tuning the magnetic field or slightly changing the RF frequency.

Cocktail Number	M/Q	lon	DUT energy (MeV)	Range (µm Si)	LET (MeV cm²/mg)
1	5.07	¹³² Xe ²⁶⁺	459	43	55.9
	4.94	⁸⁴ Kr ¹⁷⁺	316	43	34
	5	⁴⁰ Ar ⁸⁺	150	42	14.1
		²⁰ Ne ⁴⁺	78	45	5.85
		¹⁵ N ³⁺	62	64	2.97
		¹⁰ B ²⁺	41	80	1.7

The following ion cocktail from those available at UCL was used for the testing.

For each of the ions the effective LET could be increased from the LET value given in the table by tilting the test sample so that the ion beam was no longer normal (perpendicular) to the die surface.

The sample chamber has the general shape of a cylinder lying on its side and stretched vertically, with internal dimensions of 71 cm high, 54 cm wide and 76 cm deep. The opening end of the cylinder can be moved 1 m away from the cylinder on a rail system for sample installation. It also supports an internal frame for holding the test samples and contains connectors for electrical connections. During operation the complete chamber can pump down to operating vacuum in less than ten minutes. Photographs showing the chamber set up for the PCDF component testing are included in Appendix C to this report.

To set up, control and monitor the beam flux and homogeneity a box in front of the chamber contains a Faraday cup, four scintillators and two parallel plate avalanche counters (PPAC). Two additional surface barrier detectors are placed in the test chamber.

3.2 Preparation of Components

All of the component samples were serialised and then subjected to some basic parametric measurements to check that they were functional. One component of each type was retained as a control and two of the remaining components were opened using appropriate mechanical or chemical techniques to expose the die surface. After they were opened the components were again subjected to the basic parametric measurements to determine if there were any significant changes which might indicate that they had been damaged by opening.

Photographs of one opened component of each type are shown in Appendix A to this report.

3.3 Test Sockets and Printed Circuit Board Layout

The test chamber is able to take a printed circuit board up to 250×250 mm, of which an area of 250×120 mm can be scanned by the heavy ion beam. Although the remaining board area cannot be irradiated, and therefore is unusable for mounting test components, it can be used for any connectors or components needed for the biasing and monitoring of the test components.

For testing the PCDF components in the vacuum chamber a "piggy-back" configuration was used with one mother board and separate daughter boards for each component type to be tested. The mother board had four identical socket pairs into which four individual daughter boards could be plugged. The daughter boards contained the components to be irradiated and also any wire links, resistors or capacitors necessary for the correct biasing and monitoring of the test samples. A photograph of the mother board with four daughter boards is included in Appendix C to this report and is shown schematically in Appendix D.

Based on the availability of suitable sockets, and the requirements for providing additional mechanical stability for some plastic packages before opening them, the test samples were either plugged into sockets on the daughter boards or were soldered to small carrier boards which were then mounted on the daughter boards.

3.4 Biasing and Monitoring Circuit

The basic biasing and monitoring circuit was located in a box outside the vacuum chamber and had been designed to fulfil the following main functions:

- To supply to the piggy-backed daughter boards the necessary positive, negative and ground voltages for biasing the components under test.
- To monitor the currents flowing in the positive and negative supply lines.
- To allow preset limits to be set for the supply currents using controls on the monitor box.
- To remove the bias voltages from the components under test if the monitored currents exceed the preset limits.
- To indicate using LEDs outside the chamber when the preset negative and/or positive current limits have been exceeded.
- To allow the circuit to be reset from outside the vacuum chamber thereby re-applying biasing to the components under test.

It should be noted that the circuit could be switched between the different test components which were in the chamber at the same time and was used to bias and monitor only the one component which was being irradiated. Therefore if a latch-up occurred it was obvious which component had failed as only one component was being biased, irradiated and monitored at any one time. As the circuit was designed to remove the biasing before any permanent damage could occur it was possible to re-apply the bias as soon as the component which latched-up was no longer being irradiated.

The circuitry on the daughter boards was intended only to direct the bias voltages to the correct pins on the component under test and to provide any necessary load resistors or capacitors.

The biasing and monitoring circuit is shown schematically in Appendix D at the end of this document and a photograph is included in Appendix C. Part type specific information and schematics of the daughter board circuits for each component type are given in Appendix E.

4 <u>TEST PERFORMANCE</u>

4.1 Electrical Check at UCL

Immediately before the components were placed in the vacuum chamber at UCL they were subjected to a very simple electrical check based on the measurement of supply currents and, where appropriate, output voltages. This was performed to ensure that the components were functional and to allow for selection of a suitable current monitoring threshold.

4.2 <u>Heavy Ion Irradiation with Monitoring for SEL</u>

The test samples on the appropriate daughter boards were mounted four at a time on the mother board and placed in the vacuum chamber where they could be individually exposed to a calibrated heavy ion beam. Each sample was subjected to a number of different LET_{eff} levels which were obtained by using different ion species and various tilts of the die with reference to the axis of the impinging ion beam. At each LET_{eff} level the irradiation was continued until a fluence of 10^6 particles/cm² had been reached or until a latch-up had been detected. The initial and subsequent LET_{eff} levels used for the irradiation of each component were individually decided using engineering judgement together with available information covering:

- Existing SEL sensitivity results for other devices manufactured using similar technology
- Results of previous test runs on the same component at other LET_{eff} levels
- Results of testing the first component of a particular type if a second component of the same type was being tested
- Results of test runs on other PCDF components

During exposure each component was biased using conditions which were based on those which it would experience in the PCDF project and those which were most likely to support latch-up. These bias conditions were defined and agreed in the "test plan" and are shown for each component type in Appendix E of this report. During testing the supply current(s) to the irradiated component were monitored to detect any large and sudden increase which would indicate the occurrence of a latch-up. For each component type an appropriate latch-up threshold current level was selected and if the current increased above this level the voltage biasing was automatically cut off to prevent permanent device damage due to latch-up. The threshold levels were all set in the mA range and where possible were about an order of magnitude higher than the measured pre-irradiation supply current.

If the biasing to a component was automatically cut off by the monitoring circuit the irradiating heavy ion beam was closed. The biasing was then re-applied to check whether the current increase was due

to a reversible latch-up or whether permanent damage had been caused by any other effect such as device burnout, SEB, SEGR, etc. Reapplying the irradiating beam to the component with the biasing applied then allowed an assessment to be made of whether it was only noise in the system which had triggered the monitoring circuit.

Each component was tested up to an LET level at which latch-up clearly occurred, or up to a level at least twice the PCDF project required threshold of 36 MeV cm²/mg. For each component an assessment was also made of the total radiation dose which it had experienced during exposure to the heavy ion beam.

Two components of each type were exposed to the heavy ion irradiation, even though Astrium Proposal A.2000.2124-0-2 from Astrium GmbH, Ottobrunn to Astrium GmbH, Friedrichshafen required the irradiation of only one component. Testing of a second component within the originally agreed costs and schedule was possible because the test samples were opened very carefully to avoid damaging any of them and because the available beam time was used very efficiently.

All irradiation test activities were performed in accordance with the requirements of ESA/SCC Basic Specification No. 25100 except where the Astrium GmbH Irradiation Test Plan gave an alternative.

4.3 <u>Astrium GmbH, Ottobrunn Responsibilities</u>

Astrium was responsible for supplying all the necessary test samples, test boards, biasing and monitoring circuits, power supplies, and the test equipment needed for setting up and checking the test circuits. Astrium was also responsible for performing the actual testing including all controlling of the irradiation facility which could be performed using the BOARD POSITION, DATA BEAM and BEAM LINE screens on the user interface system.

4.4 UCL Responsibilities

A qualified operator for the HIF was present at all times that the beam was operational and was responsible for all operations which could not be controlled using the BOARD POSITION, DATA BEAM and BEAM LINE screens on the user interface system. The UCL operator was also responsible for ensuring that the Astrium personnel did not inadvertently misuse the system due to inadequate information or instructions.

Page: 14 of 70

5 <u>TEST RESULTS</u>

5.1 Summary of Test Results

The following table summarises the test results obtained for the individual components.

ltem No.	Part Type	Serial No.	SEL Detected?	Minimum LET _{eff} which caused SEL (if detected)	Maximum LET _{eff} used which did not cause SEL	Total Dose (over all test runs)	Comments

Notes

- A latch-up was apparently detected at an LET_{eff} of 48.1 MeV cm²/mg but this did not recur when the test was repeated at the same LET_{eff} level nor was any latch-up detected at LET_{eff} levels of 55.9 and 73.0 MeV cm²/mg. It was concluded that the latch-up detection circuit had originally been triggered in error by noise in the system.
- Latch-up was detected during two test runs at 34.0 MeV cm²/mg but no latch-up was detected at 14.1, 19.9 and 28.2 MeV cm²/mg.
- 3. Latch-up was detected during one test run at 34.0 MeV cm²/mg but not during a repeat run at the same level. An apparent latch-up (probably due to noise in the system) was detected during one run at 14.1 MeV cm²/mg but not during a repeat run at the same level or during test runs at 19.9 and 28.2 MeV cm²/mg.
- Latch-ups were detected at 14.1 and 34.0 MeV cm²/mg, but not during runs at 5.85 and 9.1 MeV cm²/mg.
- 5. A latch-up was apparently detected at an LET_{eff} of 34.0 MeV cm²/mg but this did not recur when the test was repeated at the same LET_{eff} level nor was any latch-up detected at LET_{eff} levels of 48.1 and 73.0 MeV cm²/mg. It was concluded that the latch-up detection circuit had originally been triggered in error by noise in the system.

These results indicate that there could be a latch-up problem with the following component types if they are subjected to the minimum levels of heavy ion irradiation specified for the PCDF project.

5.2 Detailed Test Results

.

A table giving details of all the irradiation test runs carried out on the sample components is given in Appendix F at the end of this report. In this table the test runs are not listed in the order in which they were actually carried out, but are ordered by Item No., Item Serial No. and LET_{eff} . Individual test sheets showing electrical conditions and results for each Item No. are included in Appendix G.

6 <u>CONCLUSIONS</u>

On the basis of the testing performed on the supplied samples it is possible to conclude that sixteen of the tested part types have an SEL LET threshold >73 MeV cm²/mg and therefore the parts meet the PCDF project requirement of 36 MeV cm²/mg.

The following four part types, listed in descending order of resistance to SEL, had a threshold below the minimum limit required for the PCDF project and therefore further assessment of the use of these parts is recommended.

- Linear Technology positive voltage regulator type 5962-8998101YA (LT1086MH/883) SEL occurred at 34.0 MeV cm²/mg but not at 28.2 Mev cm²/mg
- Analog Devices 12-bit CCD digital signal processor type AD9816JS SEL occurred at 14.1 MeV cm²/mg but not at 9.1 Mev cm²/mg

As the estimated total radiation dose seen by all the test samples was extremely low (typically 2.5 krad and a maximum of 3.5 krad) it was not considered sufficient to allow any meaningful assessment of total radiation dose effects.

Appendix D – General test schematic

Page: 42 of 70

APPENDIX E - PART TYPE SPECIFIC SCHEMATICS

- Item No.: 1
- Component Type: JANTXV2N6782
- Component Package: TO-205AF
- Irradiation Bias Conditions:

Bias Conditions:

VGS = 0V initially, then, as option, VGS = -5V for additional results using the same heavy ions

- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of VDS and ID in "ON" condition

- Item No.: 2
- Component Type: JANTXV2N6845
- Component Package: TO-205AF
- Irradiation Bias Conditions:

- Bias Conditions:
 VGS = 0V (but other VGS values could be considered)
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of VDS and ID in "ON" condition

Page: 44 of 70

• Item No.: 3

• Component Type: SNJ55ALS194J (5962-8864801EA)

- Component Package: 16-pin CERDIP
- Irradiation Bias Conditions:

- Bias Conditions:
 One port (1,2) disabled; other port enabled (3,4);
 One input low and one input high on each driver
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000 or Credence) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of ICC

Page: 45 of 70

- Item No.: 4
- Component Type: SNJ55ALS195J (5962-8864901EA)
- Component Package: 16-pin CERDIP
- Irradiation Bias Conditions:

- Bias Conditions:
 One port disabled; one port enabled;
 One receiver low and one receiver high of each pair
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000 or Credence) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of current in both lines

Issue:

Date:

Document: ITR/926-01

1

 19.07.2001

 • Item No.:
 5

 • Component Type:
 LT1086MH/883 (5962-8998101YA)

- Component Package: TO-39
- Irradiation Bias Conditions:

- Bias Conditions:
 Bias provides a 3.3V output voltage (application condition)
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of input current Measurement of output voltage

Page: 46 of 70

- Item No.: 6
- Component Type: AS5C4008F-25
- Component Package: 32-pin flatpack
- Irradiation Bias Conditions:

- Bias Options:
 None
- Electrical Tests Before and After Opening: Measurement of ICC
- Electrical Tests Before and After Irradiation: Measurement of ICC

- Item No.: 7
- Component Type: AD822AR
- Component Package: 8-pin SOIC
- Irradiation Bias Conditions:

- Bias Options: Testing could be repeated with another supply voltage, e.g. 15V
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of supply current Measurement of output voltage

- Item No.: 8
- Component Type: AD9816JS
- Component Package: 44-pin MQFP
- Irradiation Bias Conditions:

- Bias Options: None
- Electrical Tests Before and After Opening: Measurement of supply current
- Electrical Tests Before and After Irradiation: Measurement of supply current

Page: 50 of 70

- Item No.: 10
- Component Type: M55310/28-B11A 20000000
- Component Package: 4-pin SMT
- Irradiation Bias Conditions:

- Bias Options: None
- Electrical Tests Before and After Opening: Measurement of supply current Measurement of frequency
- Electrical Tests Before and After Irradiation: Measurement of supply current Measurement of frequency

- Item No.: 12
- Component Type: MIC 4452BM
- Component Package: 8-pin SOIC
- Irradiation Bias Conditions:

- Bias Options: Testing could be repeated with another supply voltage, e.g. 15V
- Electrical Tests Before and After Opening:
 Automated Test Equipment (SZ3000) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of supply current Measurement of output voltages

Page: 52 of 70

- Item No.: 13
- Component Type: 54ACTQ04LMQB
- Component Package: 20-pin CLCC
- Irradiation Bias Conditions:

- Bias Conditions:
 3 inverters "LOW"; 3 inverters "HIGH" during irradiation
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of supply currents Measurement of output voltages

Page: 53 of 70

• Item No.: 14

• Component Type: 54FCT245T (5962-9221401MRA)

- Component Package: 20-pin CERDIP
- Irradiation Bias Conditions:

- Bias Conditions:
 Bus A data to Bus B
 Half the inputs high; remaining inputs low
 Outputs enabled
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000 or Credence) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of supply current Measurement of output voltages

Page: 54 of 70

- Item No.: 15
- Component Type: JD54F38BCA (JM38510/35202BCA)
- Component Package: 14-pin CERDIP
- Irradiation Bias Conditions:

- Bias Conditions:
 2 gates with output "LOW"; 2 gates with output "HIGH" (different input conditions)
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000 or Credence) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of supply current Measurement of output voltages

Page: 55 of 70

- Item No.: 16
- Component Type: 54HCT04 (JM38510/65751BCA)
- Component Package: 14-pin CERDIP
- Irradiation Bias Conditions:

- Bias Conditions: Half the inverters "LOW"; remaining inverters "HIGH"
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000 or Credence) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of supply current Measurement of output voltages

Page: 56 of 70

- Item No.: 19
- Component Type: AD620SQ 883BQ
- Component Package: 8-pin CERDIP
- Irradiation Bias Conditions:

- Bias Options:
 Other supply conditions could be applied for additional results, e.g. ± 5V or ± 15V
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of supply currents Measurement of output voltages

Page: 57 of 70

• Item No.: 20

• Component Type: LM2991J-QML (5962-9650501 QEA)

- Component Package: 16-pin CERDIP
- Irradiation Bias Conditions:

- Bias Conditions:
 Bias provides a –9.2V output voltage (application condition)
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of supply current Measurement of output voltages

Page: 58 of 70

- Item No.: 23
- Component Type: DG406AK/883 (5962-9562301QXA)
- Component Package: 28-pin CERDIP
- Irradiation Bias Conditions:

Bias Conditions:

None of the switches are selected but maximum voltage stress is applied over half the switches. Other supply conditions can be applied, e.g. \pm 5V or \pm 15V

- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000 or Credence) using simple test program
- Electrical Tests Before and After Irradiation: Measurement of supply currents

Page: 59 of 70

- Item No.: 24
- Component Type: LM117H/883Q
- Component Package: TO-39
- Irradiation Bias Conditions:

- Bias Conditions:
 Bias provides a 23V output voltage (application condition)
- Electrical Tests Before and After Opening: Automated Test Equipment (SZ3000) using existing test program
- Electrical Tests Before and After Irradiation: Measurement of input current Measurement of output voltage
